Group by anticipation

Group by of Inner query:

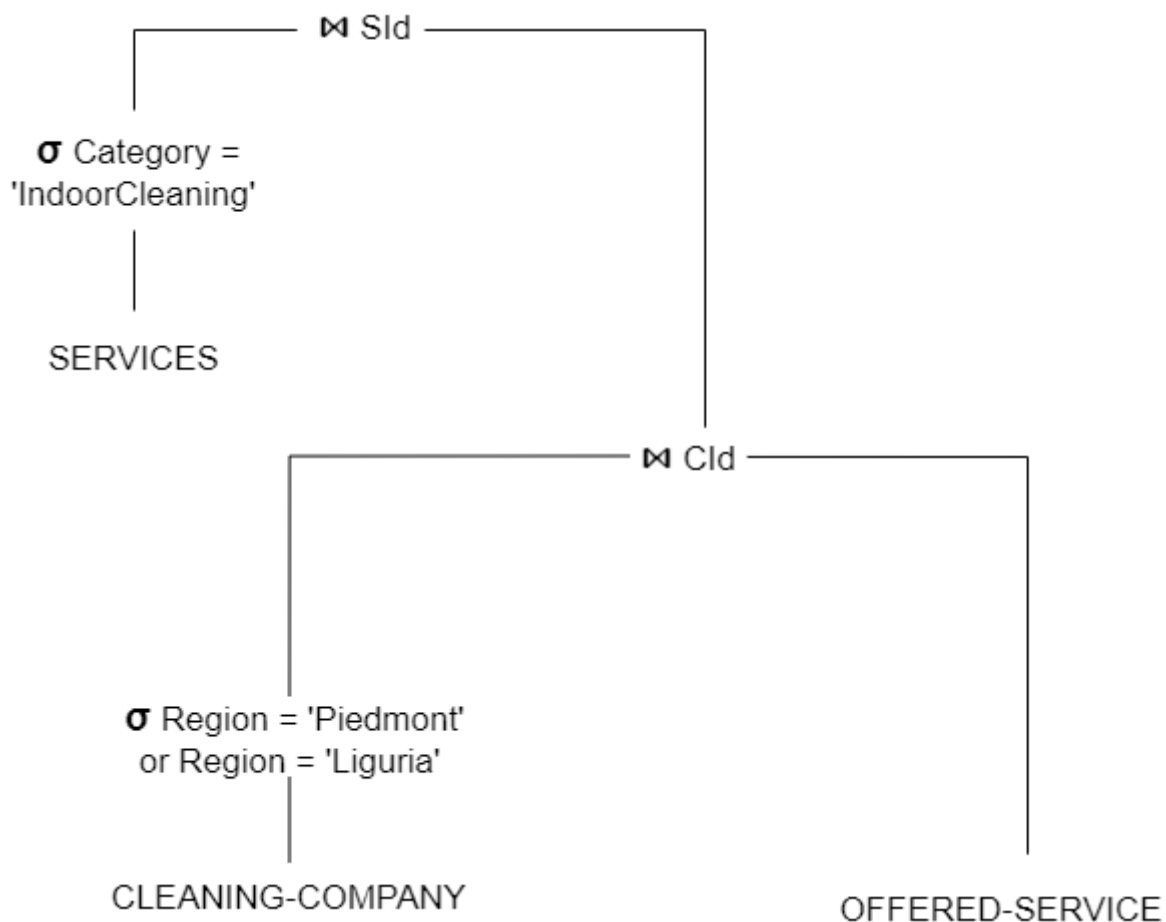

The group by and having on OS.Sld can't be anticipated. In Services subtree, there isn't the OS.Sld attribute. In the other subtrees is not allowed because the attribute Cld is needed, and the result of the group by on Sld don't include this attribute.

Group by of the outer query:

The group by and Having on Bld can't be anticipated because in any place would cause the loss of information on attributes needed for the join.

Join orders

In this SQL query, we could analyse the order of the two joins of the inner query. In particular, we could consider to change the order as in the image below, in order to filter first offered services with cleaning company in Piedmont or Liguria. The original solution has the same reduction factor, so there are no differences.

Access methods without indexes

We distinguish two types of accesses: table access full and table access full + filter. In this exercise, we have the first type for OFFERED-SERVICE, on which is not performed any filter. The other are characterized by different filters, so the access method is full + filter.

Indexes

CLEANING-SERVICE: SECONDARY B+tree Index on Date

BUILDING: SECONDARY Hash Index on City

CLEANING-COMPANY: SECONDARY Hash Index on Region

SERVICES: SECONDARY Hash Index on Category

OFFERED-SERVICES: No index

The choice of these indexes depends on the cardinality of the tables involved.

For CLEANING-SERVICE, a secondary B+tree index on Date could be useful for filtering, as the table has 10^9 tuples.

In BUILDING table, it could be useful a secondary index on the City thanks to the good reduction factor.

In CLEANING-COMPANY and SERVICES tables, there are filters with a good reduction factor, so we create indexes Hash Indexes on Region and Category.

In OFFERED-SERVICE, we could think to insert a primary b+tree index on Sld attribute, but

this attribute doesn't represent the natural order of the information, so it couldn't be useful as we hope.
